

Plant Life Cycle: Fruits and Seeds

From ovary to fruit

- The ovary of the flower contains the ovules.
- As fertilized ovules develop into seeds, the ovary wall develops into the fruit.
- In science, the term “fruit” refers to a mature ovary that contains seeds.

Pollination and Fertilization

From ovary to fruit

Fruit Types

- A fruit may be defined as a matured ovary
- There are two basic fruit types – dry or fleshy. These types arise from the development of the ovary wall (=pericarp)
- The pericarp may become dry and these form dry fruits
- The pericarp may also become soft, thick and fleshy – and these form fleshy fruits
- Dryfruits can also split in various ways (dehiscent), or not (indehiscent)

Figure 6.1 The berry, hesperidium, pepo, and pome are fruits in which at least part of the pericarp is soft and juicy. Fruits such as the follicle, legume, and capsule are characterized by the way in which they open. Achenes, grains, and nuts are dry fruits that do not split open to disperse the seed. A samara (as in elm or maple) is a winged fruit that uses wind as the dispersal agent. Blackberries and strawberries are collections of fruits that develop from the many separate carpels of a single flower. The pineapple is a multiple fruit that forms when the ovaries of individual flowers in a flower cluster fuse.

Types of fleshy fruits

Drupe
(Peach)

Pome
(Apple)

Pepo
(Cucumber)

Berry
(Tomato)

Walnuts and Pecans

Ripe fruit with green outer pericarp enclosing seed-bearing endocarp.

In pecans, the outer pericarp splits into 4 sections.

Outer pericarp layer (husk).

Hard inner layer of the pericarp.

endocarp

The shell is similar to the endocarp of a dry drupe.

Inner pericarp (shell) surrounding the seed.

2 cotyledons (halves) of seed.

Fruit dispersal

- The form of the fruit gives clues about its dispersal.
- Small, dry fruits with “wings” or “parachutes” may be wind-dispersed. Fleshy fruits are often animal dispersed. Explosive fruits can fling seeds away. Floating fruits may be water dispersed.

How Seeds Travel

Ovule to seed

Seed Components

A seed contains all of the genetic information needed to develop into an entire plant. It contains three parts.

- **Embryo**-a miniature plant which will grow when conditions are favorable.
- **Endosperm**-built in food supply for the plant.
- **Seed Coat**—Hard outer covering, protects the seed from disease and insects. Prevents water from entering the seed before the proper time.

Mature Seed

(b)

Dicot Seed Parts

Seed anatomy

Seed dormancy

- Seeds can remain dormant in the soil for long periods of time. Dormancy helps ensure that seeds only germinate when conditions are right.
- When we weed or cultivate a bare patch of soil, the weeds that sprout up immediately usually come from the “seed bank” already in the soil.

Breaking dormancy

- Seeds require moisture and the right temperature to germinate.
- In addition, some seeds germinate only after certain environmental signals:
 - Drying
 - Temperature (period of cold or heat)
 - Disruption of the seed coat

Germination: dicot

Germination: monocot
